Digital Control Systems MAE/ECEN 5473

Quadratic Optimal Control

Oklahoma State University

August 14, 2023

#### **Optimal** control

- Optimal control: Design a control that yields "best" performance with respect to some "objective function"
- Cost function (performance index):

$$J_N = \sum_{k=0}^{N} L_k(y(k), x(k), u(k), r(k))$$
(1)

Design u(k),  $k = 0, \dots, N$  such that  $J_N$  is minimized subject to

$$x(k+1) = Gx(k) + Hu(k)$$

• If  $J_N$  is to be maximized, then minimize  $-J_N$ .

#### Quadratic cost

$$J_N = \sum_{k=0}^{N} x(k)^T Q(k) x(k) + u(k)^T R(k) u(k)$$
(2)

Design parameters: Q(k) – Positive semidefinite (PSD), R(k) – Positive definite (PD)

Example  $Q(k) = C^T C.$ 

Example

Choose R(k) to be PD.

### Optimal control problems

- Given x(k+1) = Gx(k) + Hu(k) and y(k) = Cx(k), assume full state feedback, i.e., x(k) is available.
- ▶ Determine a control u(k) = f(x(k)) such that the cost function  $J_N = \sum_{k=0}^N x(k)^T Q(k) x(k) + u(k)^T R(k) u(k)$  is minimized, where Q(k) is PSD and R(k) is PD.
- An optimal control is optimal only for the selected performance index (cost function), i.e., may not be optimal for other cost functions.

#### Disclaimer

In the book,  $J_N = \frac{1}{2}x(N)^T Sx(N) + \frac{1}{2} \sum_{k=0}^{N-1} (x(k)^T Qx(k) + u(k)^T Ru(k)).$ 

This is equivalent to our notation  $J_N = \sum_{k=0}^N x(k)^T Q(k) x(k) + u(k)^T R(k) u(k) \text{ with } Q(N) = \frac{1}{2}S,$   $R(k) = \frac{1}{2}R, \ Q(k) = \frac{1}{2}Q, \ u(N) = 0.$ 

A D N A 目 N A E N A E N A B N A C N

Quiz: Why can we set u(N) = 0 in our formulation?

#### Solve optimal control

#### Principle of optimality (Richard Bellman)

If the control u(k) = f(x(k)) is optimal over the period  $0 \le k \le N$ , then it is also optimal over any horizon  $m \le k \le N$ , where  $0 \le m \le N$ .

Optimal control can be solved backwards in time.

### PoO applied to optimal control

• Define 
$$F(k) = x(k)^T Q(k) x(k) + u(k)^T R(k) u(k)$$
.

- Define  $S_m$  to be the cost from k = N m + 1 to k = N (cost to go), i.e.,  $S_m = F(N m + 1) + F(N m + 2) + \cdots + F(N)$ .
- Note  $J_N = \sum_{k=0}^N F(k)$  and  $S_m = J_N J_{N-m}$ .

#### Principle

If  $J_N$  is optimized,  $S_m$  must be optimized,  $m = 1, \cdots, N + 1$ .

- 1. Start with minimizing  $S_1 = J_N J_{N-1} = F(N)$  w.r.t. u(k).
- 2. Optimize  $S_2 = F(N-1) + F(N) = F(N-1) + S_1^*$  where  $S_1^*$  is the optimized value of  $S_1$ .

- 3. :
- 4. Continue this process until  $S_{N+1} = J_N$  is minimized.

### Example continued

▲□▶▲圖▶▲≣▶▲≣▶ ≣ のQ@

## Observations

- The optimal control is linear: u(k) = -K(k)x(k).
- The optimal control is time-varying because K(k) depends on K.

- ► The optimal control is solved backwards in time.
- The minimum of the cost function depends on the initial condition x(0). Show.

### The minimum principle

Given x(k+1) = Gx(k) + Hu(k), determine u(k) = f(x(k)) such that  $J_N = \sum_{k=0}^{N} x(k)^T Q(k) x(k) + u(k)^T R(k) u(k)$  is minimized, where Q(k) is PSD and R(k) is PD.

#### Principle

If  $u^*(k)$  is optimal and the corresponding  $x^*(k)$  is optimal, then there exists a sequence of nontrivial vectors  $\{p^*(k)\}$  such that  $u^*(k)$  is the value of u(k) that minimizes the Hamiltonian

$$H_{k} = \frac{1}{2} (x^{*}(k)^{T} Q(k) x^{*}(k) + u(k)^{T} R(k) u(k)) + p^{*}(k+1)^{T} (Gx^{*}(k) + Hu(k)).$$
(3)

Linear two-point boundary value problem

- For  $p^*(k)$ , given  $p^*(N)$ , it is solved backward in time.
- For  $x^*(k)$ , given x(0), it is solved forward in time.

optimal control algorithm: the optimal control is given by

$$u^{*}(k) = -K(k)x(k)$$
  

$$K(k) = [H^{T}P(k+1)H + R(k)]^{-1}H^{T}P(k+1)G \quad (\star)$$
  

$$P(k) = G^{T}P(k+1)[G - HK(k)] + Q(k) \quad (\star\star)$$

- 1. Start with P(N) = Q(N), K(N) = 0.
- 2. Solve for K(N-1) from  $(\star)$
- 3. Solve for P(N-1) from  $(\star\star)$  using P(N) and K(N-1)
- 4. Solve for K(N-2) from (\*) using P(N-1) from 3.
- 5. Solve for P(N-2) from  $(\star\star)$  using P(N-1) and K(N-2) from 4.

- 6. ÷
- 7. Solve for K(0) and then P(0).

#### Final comments

► The optimal cost J achieved by u\*(k) = -K(k)x(k) is J\* = min J = x(0)<sup>T</sup>P(0)x(0).

So far, only considered finite horizon problems, i.e., N is finite.

- ▶ Infinite horizon:  $N \to \infty$ , Q(k) = Q, R(k) = R.
  - P(k) in (\*\*) converges to a constant P.
     u\*(k) = -Kx(k) where K is a constant gain matrix. From (\*) and (\*\*),

$$K = [H^T P H + R]^{-1} H^T P G, P = G^T P [G - H K] + Q \Rightarrow$$

Algebraic Riccati Equation (ARE):

$$P = G^T P G + Q - G^T P H (H^T P H + R)^{-1} H^T P G$$

- Main advantage: If (G, H) is controllable, P from the ARE is PD and u(k) = -Kx(k) is stabilizing.
- ▶ If the full state x(k) is not available, design an observer based on y(k) = Cx(k) and u(k) and use the estimate  $\tilde{x}(k)$  in the feedback control  $u(k) = -K\tilde{x}(k)$ .

### Example revisited

## A "very practical" introduction to Kalman filter (KF)

#### Motivation

Reconstruct state from measurements & inputs (similar to an observer)

Reduce the noise impact in the estimate ("filtering")

#### Setup

- Dynamical system:  $x_k = F_k x_{k-1} + G_k u_k + B_k w_k$
- Measurement:  $z_k = H_k x_k + v_k$  (observation model)

$$\blacktriangleright$$
  $x_k$ ,  $F_k$ ,  $u_k$ ,  $w_k$ ,  $v_k$ :

Objective: Given the noisy measurements z<sub>k</sub> and input u<sub>k</sub>, reconstruct x<sub>k</sub>

### KF equations

Assumption: {x<sub>0</sub>, w<sub>1</sub>, w<sub>2</sub>, · · · , v<sub>1</sub>, v<sub>2</sub>, · · · } are mutually independent.

Notation. x̂<sub>n|m</sub>: estimate of x at time step n (x<sub>n</sub>) given observations up to time step m (i.e., {z<sub>1</sub>, · · · , z<sub>m</sub>}). What is x̂<sub>k|k</sub>?

 $P_{k|k}$ : error covariance of  $\hat{x}_{k|k}$ , measure of estimation accuracy

►  $\mathcal{N}(\mu, \Sigma)$ : Normal distribution with mean  $\mu \in \mathbb{R}^d$  and covariance  $\Sigma \in \mathbb{R}^{d \times d}_{>0}$  (PD matrix)

## KF algorithm

KF equations: start with  $\hat{x}_{0|0} \sim \mathcal{N}(x_0, P_{0|0})$ At time step  $k, k \ge 1$ , recursively implement

1. Prediction step (no measurements involved):

$$\hat{x}_{k|k-1} = F_k \hat{x}_{k-1|k-1} + G_k u_k$$
$$P_{k|k-1} = F_k P_{k-1|k-1} F_k^T + \frac{B_k Q B_k^T}{B_k Q B_k^T}$$

2. Update step (incorporate measurements):

$$\begin{split} \tilde{y}_{k} &= \underbrace{z_{k}}_{measured} - \underbrace{H_{k}\hat{x}_{k|k-1}}_{predicted} \\ S_{k} &= H_{k}P_{k|k-1}H_{k}^{T} + R, K_{k} = P_{k|k-1}H_{k}^{T}S_{k}^{-1}, \\ \hat{x}_{k|k} &= \hat{x}_{k|k-1} + K_{k}\tilde{y}_{k} \\ P_{k|k} &= (I - K_{k}H_{k})P_{k|k-1} \leq P_{k|k-1}? \end{split}$$

Conclusions/Results (without proof)

▶ If  $\hat{x}_{0|0}$ ,  $P_{0|0}$  accurately reflect the true distribution of  $x_0$ , then

- ► KF is the optimal linear filter and minimizes the trace of P<sub>k|k</sub>, if a) the model perfectly matches the real system, b) the noise is uncorrelated, c) R and Q are known exactly.
- If the noise (w<sub>k</sub>, v<sub>k</sub>) are not normal distribution, KF is still the best linear filter.
- If the dynamical system (F<sub>k</sub>, H<sub>k</sub>) is observable, the estimation error E(x<sub>k</sub> − x̂<sub>k|k</sub>) remains bounded.

Connection to current observer: Remove the prediction step
